Multifractal analysis of the spiral density waves observed in simulated stationary convection. In the convection of a non-convecting fluid in a rotating annulus the spiral density waves, usually regarded as simple acoustic spiral waves, turn out to be multifractal and cannot be described by a single scaling exponent, in contrast to the theoretical prediction in the framework of the Goldreich-Schubert-Fricke (GSF) theory. Rather, the logarithm of the wave amplitudes (characteristic of log-normal distribution functions) as well as the usual scaling exponent (characteristic of a log-normal distribution function) scale in the same way as the action spectrum peaks (characteristic of a lognormal distribution function). The main difference with respect to the theory is that the characteristic number of harmonics is constant along the entire spiral wave (characteristic of a lognormal distribution function). ** * Copyright (c) 2017-present, Facebook, Inc. * All rights reserved. * * This source code is licensed under the BSD-style license found in the * LICENSE file in the root directory of this source tree.
